

Lecture 8:  
Hypothesis Testing for a Proportion  
STAT 310, Spring 2023

# Hypothesis Test for a Proportion

## Key components:

- ▶ Null hypothesis:

$$H_0 : p = p_0$$

- ▶ Alternative hypothesis (use one of these):

$$H_A : p > p_0 \text{ (one-sided, upper-tail)}$$

$$H_A : p < p_0 \text{ (one-sided, lower-tail)}$$

$$H_A : p \neq p_0 \text{ (two-sided)}$$

- ▶ Test statistic:

$$z = \frac{\text{observed value} - \text{null value}}{\text{SE}} = \frac{\hat{p} - p_0}{\sqrt{\frac{p_0(1-p_0)}{n}}}$$

- ▶ A rule to either reject or not reject  $H_0$

# Hypothesis Testing Concept

The approach to hypothesis testing is as follows:

1. Assume that  $H_0$  is true.  $H_0$  usually represents a skeptical position, or a perspective of no difference or change in the parameter of interest.
2. Reject  $H_0$  only if the data provide strong evidence in support of the alternative claim in  $H_A$ .

# Hypothesis Testing Concept

The hypothesis testing framework can be found in the US court system, where innocence is assumed until proven guilty.<sup>1</sup>

$H_0$ : The defendant is innocent.

$H_A$ : The defendant is guilty.

The jurors consider whether the evidence is convincing enough to convict the defendant (reject  $H_0$ ).

## $p$ -value

A  **$p$ -value** is the probability of obtaining a test statistic as extreme, or more extreme (in the direction of the alternative), than the observed value of the test statistic, assuming that  $H_0$  is true.

# $p$ -value

Decision rule using the  $p$ -value:

- ▶ If  $p\text{-value} < \alpha$ , then reject  $H_0$ .
- ▶ If  $p\text{-value} > \alpha$ , then do not reject  $H_0$ .

$\alpha$  is called the **significance level**. The most common value for  $\alpha = 0.05$ , but other values are also sometimes used such as  $\alpha = 0.01$ .

## $p$ -value

- ▶ When the  $p$ -value  $< \alpha$  (we reject  $H_0$ ) the result is said to be **statistically significant**.
- ▶ In other words, a result is statistically significant when it is unlikely to of occurred by random chance, assuming that the null hypothesis is true.
- ▶ The smaller the  $p$ -value, the stronger the data favor  $H_A$  over  $H_0$ .

# Computing $p$ -values

One-sided test (upper-tail):

$$H_0 : p = p_0$$

$$H_A : p > p_0$$

Test statistic:

$$z = \frac{\hat{p} - p_0}{\sqrt{\frac{p_0(1-p_0)}{n}}}$$

$$p\text{-value} = 1 - \text{pnorm}(z)$$

Reject  $H_0$  if  $p\text{-value} < \alpha$

# Computing $p$ -values

One-sided test (lower-tail):

$$H_0 : p = p_0$$

$$H_A : p < p_0$$

Test statistic:

$$z = \frac{\hat{p} - p_0}{\sqrt{\frac{p_0(1-p_0)}{n}}}$$

$$p\text{-value} = \text{pnorm}(z)$$

Reject  $H_0$  if  $p\text{-value} < \alpha$

# Computing $p$ -values

Two-sided test:

$$H_0 : p = p_0$$

$$H_A : p \neq p_0$$

Test statistic:

$$z = \frac{\hat{p} - p_0}{\sqrt{\frac{p_0(1-p_0)}{n}}}$$

$$p\text{-value} = 2 * \text{pnorm}(-\text{abs}(z))$$

Reject  $H_0$  if  $p\text{-value} < \alpha$

# Conditions

A hypothesis test for a proportion is valid if the following conditions are satisfied:

- ▶ The data were collected using simple random sampling
- ▶  $np_0 \geq 10$  and  $n(1 - p_0) \geq 10$

These conditions ensure that the Central Limit Theorem holds. So, assuming that  $H_0$  is true, the sampling distribution for  $\hat{p}$  is approximately normal with mean  $p_0$  and standard error  $\sqrt{p_0(1 - p_0)/n}$ .

## Example

A simple random sample of 1,028 US adults in March 2013 found that 56% support nuclear arms reduction. Does this provide convincing evidence that a majority of Americans support nuclear arms reduction?

- (a) Write the null and alternative hypothesis for a one-sided test.

$$H_0 : p = 0.5$$

$$H_A : p > 0.5$$

- (b) Check the conditions for the hypothesis test.

► Data come from a random sample.

$$\text{► } np_0 = 1028(0.5) = 514 \geq 10$$

$$n(1 - p_0) = 1028(1 - 0.5) = 514 \geq 10$$

Yes, the condition are satisfied.

- (c) Calculate the test statistic.

$$z = \frac{\hat{p} - p_0}{\sqrt{\frac{p_0(1-p_0)}{n}}} = \frac{0.56 - 0.5}{\sqrt{\frac{0.5(1-0.5)}{1028}}} = \frac{0.06}{\sqrt{\frac{0.25}{1028}}} = 3.85$$

R command: `0.06 / sqrt(0.25 / 1028)`

## Example

scientific notation in R:

$$5.9e-05 = 5.9 \times 10^{-5} = 0.000059$$

A simple random sample of 1,028 US adults in March 2013 found that 56% support nuclear arms reduction. Does this provide convincing evidence that a majority of Americans support nuclear arms reduction?

- (d) Calculate the  $p$ -value and make a decision using  $\alpha = 0.05$  significance level.

$$\begin{aligned} p\text{-value} &= P(Z > 3.85) \\ &= 1 - P(Z < 3.85) \\ &= 1 - \text{pnorm}(3.85) \\ &= \boxed{0.000059} \end{aligned}$$

Since  $p\text{-value} < 0.05$ , we reject  $H_0$

- (e) What is the conclusion of the test in the context of the data?

The data provide strong evidence that a majority of Americans support nuclear arms reduction.

# Decision Errors

Hypothesis	Decision	
	Do not reject $H_0$	Reject $H_0$
$H_0$ true	✓	type 1 error
$H_A$ true	type 2 error	✓

The significance level of the test,  $\alpha$ , is the probability of a type I error (probability of rejecting  $H_0$  when  $H_0$  is true).

# Decision Errors

In a US court, the defendant is either innocent ( $H_0$ ) or guilty ( $H_A$ ).  
What does a type I error represent in this context? What does a type II error represent?

$H_0$  : The defendant is innocent.

$H_A$  : The defendant is guilty.

Type 1 error: The defendant is actually innocent, but the jury decides guilty.

Type 2 error: The defendant is actually guilty, but the jury decides innocent.
